The dissertation was conducted at the Department of Zoology at the University of Leiden.

The main topic of this work was to characterize the demographics of birds in the Wetlands of Leiden. This type of work, for example, due to the very large number in the form of coastal wetlands, has been very important. The work has been done on the identification of individual birds, mostly of species that are sensitive to the presence of other species or to the presence of other birds. In order to achieve the intended purpose, it was necessary to study the position as places to observe birds. Understanding the number of birds observed in the population of Wetlands of Leiden was very important to understand the behavior of birds in the area. In the present study, we have identified the position of the birds in the Wetlands of Leiden. This research was conducted in the population of birds in Leiden. The results of this study may help to understand the behavior of birds in this area.
